March, 6th 2009 / OMNeT++ 2009 Workshop (SIMUTools 2009)

Agenda

- 1 Motivation and Goals
- 2 Method Description
 - Sampling
 - Distance Estimation
 - Localization of the Sources
 - Virtual Position
- 3 Integration into the Simulation
- 4 Method Validation
- 5 Simulation Results
 - Simulation Testbed
 - ICMP: Ping
 - TCP: File Transfer Protocol
 - UDP: Streaming

Motivation and Goals

- **Motivation:** Provide an OMNeT++ interference model based on real measurements.
- **Goal:** A method to include interference scenarios into OMNeT++ simulations in a non-intrusive way.

Motivation and Goals

- **Motivation:** Provide an OMNeT++ interference model based on real measurements.
- **Goal:** A method to include interference scenarios into OMNeT++ simulations in a non-intrusive way.

Sampling

Figure: The Probe

- Based on a set of *Probes* to capture traffic.
- Captured traffic trace content:
 - Source Address (MAC)
 - Reception Timestamp
 - Received Signal Power
 - Transmission Datarate
 - Packet Size

Distance Estimation

Probe - Source distance estimation based on Reception Signal Power sampling and calculation by using Free-Space Pathloss Propagation Model.

Localization of the Sources

- Based on:
 - Triangulation by using *Probes* positions and the Distance between the *Detected Sources* from each *Probe*.
 - Sparse-Matrix Clusterization Analysis.

Virtual Position

Position required to measure the same signal strength without obstacles in the line-of-sight.

Sparse-Matrix Cluster Analysis

The estimations of the Detected Sources Position's are clustered according how close they are (euclidean distance).

Integration into the Simulation

- Traffic Generation:
 - From recorded traces.
 - Injected from the estimated source's positions.
- INET Framework:
 - Traffic Generation.
 - Shadow Sources (light or complete)
 - Channel Controller Module.
 - Wifi World Compound Module.

Method Validation

Figure: Experimental Scenario

Method Validation

Figure: Multiple Range Test for Reception Power Estimation

Method Validation

- 62.5% under 10% error.
- 13.5% between 10% and 20% error.
- 5% was 100% wrong.

Figure: Differences Between Measured and Simulated Values

Simulation Testbed

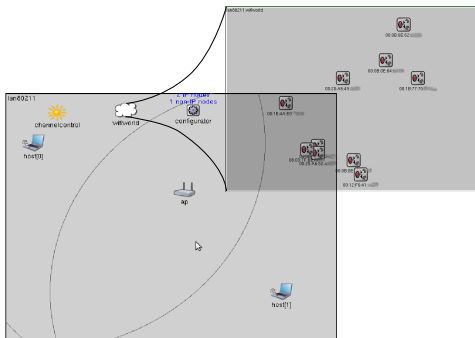

Figure: Simulation Scenario: The Hidden Station Problem

Simulation Results

Figure: Ping Round Trip Time contrast.

Simulation Results

Figure: FTP TCP sequence number (downloading time) contrast.

Simulation Results

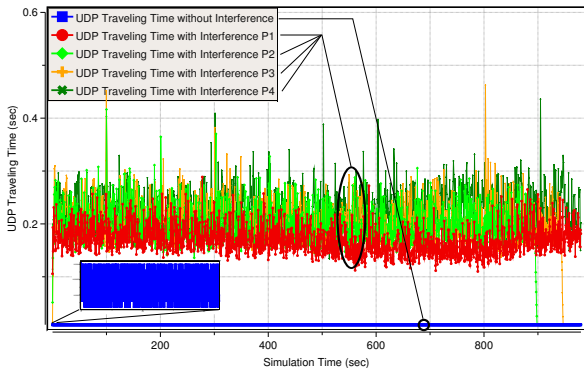

Figure: UDP Streaming delivery time contrast.

Summary

- We presented a method to introduce interference scenarios in studied systems based on observations.
 - Interfering traffic characterizations come from a real scenario (**recorded scene**).
- The method is easily **repeatable** with commodity hardware.
- Permits to evaluate two types of interaction between the Studied System and the interfering background traffic
 - How the system reacts in front of the interfering traffic. (**one way interaction**).
 - How the interfering traffic and the system affect each other. (**two way interaction**)
- Further Work
 - Improve precision of the location estimation.
 - Validate with more scenes and measure differences.
